

From a forecast to an order

Sina Mirshahi · JKU Linz · 03.10.2026

Work in pairs. Keep this as your own notes.

1. Choose a forecast

Product and channel: _____

Window: Spring / Summer / Christmas Method: _____

Evidence: average miss _____ units; bias _____ units.

A different season or channel changed our choice because: _____

Before trusting this result, we would check: _____

2. Calculate an order

Five weekly forecasts: $180 + 190 + 210 + 200 + 220 =$ _____ units.

Add safety stock of 148: stock target = _____ units.

Stock on shelf = 300; already on order = 500.

Order now = stock target minus those 800 units = _____ units.

Round teaching numbers. Assume no backorders, fixed lead time and scheduled arrivals.

3. Choose a stock policy

Product: _____

Setting	Cycle service target	Average stock, units	Fill rate	Stockout weeks
A				
B				

We would trial setting _____ because: _____

We accept this consequence: _____

Before using it in a business, we would check: _____

Remember: cycle service is a probability of no stockout; fill rate is the share of units served. A stock target is not the quantity to order.
